Datawire

The Datawire Solution: Datawire “*Classic*” and Datawire Rapid Connect

Datawire offers two different networks that can be used to connect to Fiserv’s processing platforms.

1) Datawire “*Classic*” Network
2) Datawire Rapid Connect Network

When is the “Datawire Classic” network used?

The Datawire Classic network is used when connecting directly to the Fiserv front ends (e.g. Buypass, Nashville, North, Omaha, Compass, TeleCheck) using the front end’s native message specification (e.g ISO8583, ATL105, ISO Dual, VP Term, EDC, ETC). Product connectivity options available include APIs (Java, XML, DLL, COM, Linux), NAM (Serial and IP), and Micronode

When is the Datawire Rapid Connect network used?

The Datawire Rapid Connect environment is used when connecting directly to the Fiserv Rapid Connect platform, as an intermediary to connect to the Fiserv front ends. Product connectivity options available include XML and SOAP APIs, and the NAM (IP).

Product Connectivity Options

What is the Datawire API?

- A simple and secure interface provided to the client (merchant/vendor/gateway) that integrates the POS/POI/Website/Gateway system with the Datawire Secure Transport network. The API comes in several different programming languages to support multiple development environments for every client solution.
    - The API wraps each transaction with a layer of security, authentication parameters and routing information.
    - The API then communicates via TLS from the POS/POI/Gateway through the client’s IP provider to the Datawire Secure Transport network.
    - The API can support any operating environment, as it is available in multiple programming languages.
    - The API can be used for any client solution.
- **Recommendation**: The best option for POS/POI/Website/Gateway solutions. Although effort is minimal, some development work is required.

What is the Datawire NAM (Network Access Module)?

- The NAM is a Windows-based stand-alone application meant to be installed on the same system as a Windows-based POS system. The NAM interfaces with the Windows-based POS application and performs the transfer to the appropriate platform. The NAM is a stand-alone module that needs to be installed on the same system the Windows-based POS application resides. Like the API, the NAM receives a fully formatted message and wraps each transaction with a layer of security, authentication and routing. The NAM then communicates via TLS from the POS device through the merchant’s IP provider to the Datawire Secure Transport network
- **Recommendation**: A great option for Windows-based solutions that need a quick-to-market solution that have an existing certification to the Fiserv platform.

What is the Datawire Micronode?

- The MicroNode is an external piece of hardware, similar to a router that converts an analog dial message into the IP protocol so the message can be transported over the Datawire Secure Transport Network. It is a plug-and-play device that can be easily installed at the merchants’ locations. The MicroNode receives the fully formatted transaction, converts the dial communication to IP; then like the API and NAM, wraps the transaction with a layer of security, authentication and routing. The MicroNode then communicates via TLS through the merchant’s IP provider to the Datawire Secure Transport network The MicroNode is typically used within the petroleum market space.

- **Recommendation**: A great option for petroleum based clients, as a replacement or upgrade where an IP solution would be cost prohibitive.

Datawire Secure Transport *Classic* APIs - Which to Choose

API	O/S	Programming Languages	Supported Client Types		Distribution Format (binary package and source package)	Pros	Cons
			IP Terminals /Mobile Devices/ PC POS	Website /Gateway			
JAVA	Any	JAVA	✓	✓ *	Packages contains both source and binary.	Faster development. Developer just calls required methods/functions. API handles all communication to Datawire including Service Discovery/Ping/URL failover	Binary must be installed on the applicable environment. Application has less control on how many local resources are being managed (memory, threads, and connection).
XML	Any	Any	✓	✓	N/A	Full control over functionality. No Datawire API binary needs to be installed on client’s environment	Potentially longer integration / certification process compared to COM/DLL/JAVA/LINUX API.
DLL	Windows	C/C++, C#, VB, VB.NET	✓	✓ *	Distributed in binary package only	Faster development. Developer just calls required methods/functions. API handles all communication to Datawire including Service Discovery/Ping/URL failover	Binary must be installed on the applicable environment. Application has less control on how many local resources are being managed (memory, threads, and connection).
COM	Windows	Any language supporting COM (C/C++, C#, VB, VB.NET, etc.)	✓	✓ *	Distributed in binary package only		
LINUX	Unix / Linux	C/C++, Scripting languages (E.g. Perl, PHP, Python, etc.)	✓	✓ *	Distributed in source package only		

Note* The Datawire API can be safely used in website / gateway’s multi-threaded environment. If a gateway requires more control over how resources are being managed, they can use the XML API.

For more details about these APIs, please contact: **securetransport.integration@fiserv.com**

To integrate with Datawire as a vendor/gateway, please contact: **IntegratedPartners@fiserv.com**

To integrate with Datawire as a merchant, please contact: **Sales Representative or Account Manager**
